

1.Objective

The objective of this Data Profiling Report is to evaluate the quality and readiness of the Global Superstore dataset before performing data cleaning, SQL analysis, Python processing, Excel reporting, and Power BI dashboard development. The dataset is assessed for missing values, duplicate records, data type consistency, unnecessary columns, and overall data quality to ensure reliable and accurate business analysis.

2. Dataset Summary

Property	Value
Dataset name	Global Superstore
Business domain	retail
Dataset type	Transactional sales data
Total rows	51,290
Total columns	27
Source	Kaggle
Tools used	Microsoft excel

3.Data profiling

This section presents the data quality assessment performed on the Global Superstore dataset. The dataset was analyzed to identify missing values, duplicate records, validate data types, review unnecessary columns, and determine the cleaning actions required before analysis.

Missing value analysis

Objective

The objective of this analysis is to identify missing or blank values that could affect data quality, reporting accuracy, and business analysis.

Methodology

The dataset was examined in Microsoft Excel using filters and blank cell checks across all columns to identify missing values.

Result

Checks	Result
Total column checked	27
Missing values	No
Columns affected	None
Action taken	No action required

Observation

No missing values were identified in any of the 27 columns. The dataset is complete and does not require any missing value treatment before analysis.

Business Impact

Since there are no missing values, business metrics such as Total Revenue, Profit, Customer Count, and Order Count can be calculated accurately without requiring data imputation or row removal.

Conclusion

The dataset successfully passed the missing value validation and is suitable for further analysis.

Duplicate Record Analysis

Objective

The objective of this analysis is to identify completely duplicate transaction records that could lead to incorrect business reporting and duplicate counting.

Methodology

The entire dataset was checked using the Remove Duplicates feature in Microsoft Excel with all columns selected. This method verifies whether any records are completely identical across every column.

Results

Check	Result
Total Rows checked	51290
Duplicate rows found	0
Duplicate records removed	0
Action taken	No action required

Observation

No completely duplicate records were found in the dataset. Every transaction record is unique when all columns are considered together.

Business Impact

The absence of duplicate records ensures accurate calculation of key performance indicators such as Total Sales, Total Profit, Total Orders, and Customer Count without the risk of double-counting.

Conclusion

The dataset successfully passed the duplicate record validation and is ready for further processing.
